EXECUTIVE SUMMARY

The Best Available Retrofit Technology (BART) program is part of the larger effort under the federal Clean Air Act Amendments of 1977 to eliminate human-caused visibility impairment in all mandatory federal Class I areas. Sources that are required to comply with the BART requirements are those sources that:

1. Fall within 26 specified industrial source categories.  
3. Have the potential to emit more than 250 tons per year (tpy) of one or more visibility impairing compounds.  
4. Cause or contribute to visibility impairment within at least one mandatory federal Class I area.

Tesoro Refining and Marketing Company (Tesoro) operates a petroleum (a.k.a. oil) refinery on March Point near Anacortes, Washington. The petroleum refining process results in the emissions of particulate matter (PM), sulfur dioxide (SO$_2$), volatile organic compounds (VOCs), and nitrogen oxides (NO$_X$). All of these pollutants are visibility impairing.

Petroleum (oil) refineries are one of the 26 listed source categories. Construction on the Tesoro refinery began in 1955 with commercial operation starting a year later. Additional units started operation in 1963-1964 and during a major expansion in 1971. The BART-eligible emission units at the refinery have the potential to emit more than 250 tpy of SO$_2$, NO$_X$, and PM. Fourteen of the 26 combustion units at the plant are BART-eligible. A number of the crude oil and oil product storage tanks are BART-eligible as sources of VOC. VOC emissions were not evaluated for visibility impairment or BART control technology due to the inability of the visibility model to evaluate visibility impact of VOCs. The combustion units are the major sources of visibility impairing pollutants from the oil refinery.

Modeling of visibility impairment was done following the Oregon/Idaho/Washington/EPA Region 10 BART modeling protocol. Modeled visibility impacts of baseline emissions show impacts on the 8th highest day in any year (the 98th percentile value) of greater than 0.5 deciviews (dv) at five Class 1 areas. The highest impact was 1.72 dv on Olympic National Park. Modeling showed that on the most impacted days at Olympic National Park, approximately 57 percent of the visibility impairment is due to NO$_X$ emissions and 41 percent is due to SO$_2$ emissions.

Tesoro prepared a BART technical analysis following Washington State’s BART Guidance.

The Washington State Department of Ecology (Ecology) has determined BART at the Tesoro refinery for PM/PM$_{10}$, SO$_2$, and NO$_X$, as depicted in Table ES-1.

---

1 Modeling protocol available at [http://www.deq.state.or.us/aq/haze/docs/bartprotocol.pdf](http://www.deq.state.or.us/aq/haze/docs/bartprotocol.pdf).
- BART for PM/PM$_{10}$ (all particulates) is the use of refinery fuel gas or natural gas for fuel and the current combination of emission controls on Unit F-304.
- BART for SO$_2$ is the elimination of routine use of fuel oil in Unit F-103 and meeting current requirements on sulfur content of refinery fuel gas.
- BART for SO$_2$ for Unit F-304 is the continued use of current wet scrubber emission controls.
- BART for NO$_X$ is based on continued use of the existing burners and controls except for Unit F-103 which will install new ultra-low-NO$_X$ burners.

The BART controls selected by Ecology will result in a visibility improvement at Olympic National Park of less than half of a deciview.

1. INTRODUCTION

This document is to support Ecology’s determination of the Best Available Retrofit Technology (BART) for the Tesoro Refining and Marketing Company (Tesoro) petroleum (a.k.a. oil) refinery on March Point near Anacortes, Washington.

The Tesoro refinery processes crude oil to produce refined oil products, including ultra low sulfur diesel oil, jet fuel, #6 fuel oil, and gasoline. Fourteen of the 26 process heaters, flares, and boilers, plus two cooling towers at the plant are BART-eligible. The primary emission units of concern are the process heaters, boilers, and flares. The process heaters, boilers, and flares emit \( \text{SO}_2 \) and \( \text{NO}_X \). Direct PM emissions from BART-eligible units are low because almost all of them combust either refinery fuel gas or natural gas. Only one BART unit is currently permitted to use fuel oil.

Eleven of the 74 storage tanks are also BART-eligible sources of VOCs. The CALPUFF model used to evaluate visibility impairment cannot model VOCs. Ecology directed that VOC emissions BART-eligible storage tanks and other units not be evaluated for visibility impact or BART control technology. The BART determination for the Tesoro refinery focuses only on PM, \( \text{SO}_2 \) and \( \text{NO}_X \).

1.1 The BART Analysis Process

Tesoro and Ecology used the United States Environmental Protection Agency’s (EPA’s) BART guidelines contained in Appendix Y to 40 CFR Part 51, as annotated by Ecology, to determine BART. The BART analysis protocol reflects utilization of a 5-step analysis to determine BART for \( \text{SO}_2 \), \( \text{NO}_X \), and \( \text{PM}_{10} \). The five steps are:

1. Identify all available retrofit control technologies.
2. Eliminate technically infeasible control technologies.
3. Evaluate the control effectiveness of remaining control technologies.
4. Evaluate impacts and document the results.
5. Evaluate visibility impacts.

The BART guidance limits the types of control technologies that need to be evaluated in the BART process to available control technologies. Available control technologies are those which have been applied in practice in the industry. The State can consider additional control techniques beyond those that are ‘available’, but is not required to do so. This limitation to available control technologies contrasts to the Best Available Control Technology (BACT) process where innovative technologies and techniques that have been applied to similar flue gases must be considered.

As allowed by the EPA BART guidance, Ecology has chosen to consider all five factors in its BART determinations. To be selected as BART, a control has to be available, technically feasible, cost effective, provide a visibility benefit, and have a minimal potential for adverse non-
air quality impacts. Normally, the potential visibility improvement from a particular control technology is only one of the factors weighed for determining whether a control constitutes BART. However, if two available and feasible controls are essentially equivalent in cost effectiveness and non-air quality impacts, visibility improvement becomes the deciding factor for the determination of BART.

1.2 Basic Description of the Tesoro Refinery

The Tesoro refinery purchases crude oil on the open market for processing into a variety of petroleum products, including gasoline and ultra low sulfur diesel. Current refinery throughput is approximately 115,000 barrels per day of crude oil. Crude oil is heated and sent to the crude distillation unit where the crude oil is separated into various fractions based on boiling point of the hydrocarbons. The various crude fractions are sent for further processing and refining in other units of the plant. De-asphalted heavy oil from the crude unit is hydrotreated prior to being sent to the Fluid Catalytic Cracking Unit (FCCU) to be split into lighter fractions for blending. The refinery also produces heavy fuel oil (a.k.a. #6 oil or bunker C) and paving asphalts. Figure 1-1 is a simplified process flow diagram of the overall refinery process.

Catalyst used in the FCCU is regenerated in a separate regenerator unit. In the regenerator unit, the carbon, sulfur and other impurities are burned off the catalyst. The exhaust gas from the regenerator is routed to the two carbon monoxide boilers (F-302, CO Boiler No. 1 and F-304, CO Boiler No. 2) to be combusted and the energy recovered. Exhaust gas from the two carbon monoxide boilers is routed to a single Flue Gas Scrubber for particulate and SO₂ control.

The principle air pollution control authority for this facility is the Northwest Clean Air Agency (NWCAA).

1.3 BART-Eligible Units at the Tesoro Refinery

Fourteen of the 26 process heaters, flares, and boilers and the two cooling towers at the Tesoro refinery are BART-eligible. This means that these 14 emission units have the potential to emit more than 250 tpy of SO₂, NOₓ, and PM/PM₁₀ and commenced operation within the 15-year BART period. The refinery was constructed during 1955-1956 and reported to have begun commercial operation in 1956.

Table 1-1 identifies the BART-eligible units and the emissions used in the BART modeling.

Tesoro and Ecology reviewed the currently installed and potential controls for all BART-eligible emission units listed above. Tesoro’s review was focused on the combustion units because of the contribution of these units to visibility impairment and availability of emission controls.

---

4 The 15-year period ending with August 7, 1977, the date of passage of the Clean Air Act amendments of 1977.
Some of the combustion units listed above have been subject to BACT review as part of projects to upgrade or increase plant production capacity. Others have had emission controls added to comply with federal hazardous air pollutant control requirements or to reduce ambient air quality impacts of other projects at the refinery. The results of these actions are incorporated in the modeled emission rates shown in Table 1-1.

1.3 Visibility Impact of BART-Eligible Units at the Tesoro Refinery

Emission units that meet the source category, age, and potential to emit criteria are “BART-eligible.” To be “subject to BART,” the actual emissions from the “BART-eligible” units at the facility must “cause or contribute” to visibility impairment within at least one mandatory federal Class I area. Ecology has adopted the “cause and contribute” criteria that EPA suggested in its guideline. BART-eligible units at a source cause visibility impairment if their modeled visibility impairment is at least 1.0 deciview (dv). Similarly, the criterion for contributing to impairment means that the source causes a modeled visibility change of 0.5 dv or more.

Class I area visibility impairment and improvement modeling was performed by Tesoro using the BART modeling protocol developed by Oregon, Idaho, Washington, and EPA Region 10. This protocol uses three years of metrological information to evaluate visibility impacts. As directed in the protocol, Tesoro used the highest 24-hour emission rates that occurred in the 3-year period to model its impacts on Class I areas.

Modeled visibility impacts of baseline emissions show impacts on the 8th highest day in any year (the 98th percentile value) of greater than 0.5 deciviews (dv) at five Class 1 areas. The highest impact was 1.72 dv at Olympic National Park. Modeling showed that on the most impacted days at Olympic National Park, approximately 57 percent of the visibility impairment is due to NOX emissions and 41 percent is due to SO2 emissions. For more information on visibility impacts of this facility, see Section 3 below.

---

5 A copy of the modeling protocol is available at [http://www.deq.state.or.us/aq/haze/docs/bartprotocol.pdf](http://www.deq.state.or.us/aq/haze/docs/bartprotocol.pdf).
2. BART TECHNOLOGY ANALYSIS

The Tesoro BART technology analysis was based on the 5-step process defined in BART guidance and listed in Section 1.1 of this report. The first subsection below deals with an overview of the controls evaluated for combustion units, the second with, evaluation of plant-wide SO₂ controls and specific controls on individual combustion units, and the third with controls on the cooling towers. The latter two sections provide an overview of the potentially feasible emission controls evaluated by Tesoro followed by Tesoro’s BART proposal.

In Tesoro’s evaluation of costs in the 2008 BART analysis, they assumed that all control installations would occur at a regularly scheduled maintenance turn-around. These are the costs presented in sections 2.2 and 2.3. Tesoro subsequently submitted additional cost analyses for implementation of the BART controls on 5 units at other than a regularly scheduled maintenance turn-around. This is discussed in Section 2.4.

2.1 Controls Evaluated for Combustion Units

The Tesoro refinery has 14 fuel combustion units subject to BART. The three subsections below provide an overview of the NOₓ, SO₂, and PM/PM₁₀ control techniques that were evaluated by Tesoro. While the units differ in firing rate, usage, and specific design features, most of the NOₓ, SO₂, and PM/PM₁₀ controls could be used on all units.

2.1.1 NOₓ Controls Evaluated for All Combustion Units

There are a variety of controls that can be used for reducing the quantity of NOₓ emitted to the atmosphere from the process heaters and CO Boiler which are subject to BART. Specifically, the company evaluated eight different technologies, including variations of several of them. NOₓ emissions control from refinery fuel gas and flue gas combustion can be achieved with eight technologies or combinations of technologies.

- Flue gas recirculation (FGR)
- Low-NOₓ burners (LNBs)
  - Staged-air LNBs
  - Staged-fuel LNBs
- Ultra-low-NOₓ burners (ULNBs)
- Selective non-catalytic reduction (SNCR)
  - SNCR
  - LNBs + SNCR
  - ULNBs + SNCR
- Selective catalytic reduction (SCR)
  - SCR
  - LNBs + SCR
  - ULNBs + SCR
- LoTOX™ process (evaluated only for Unit F-304, CO Boiler No. 2)
- Sulfur Recovery Unit with Tail Gas Unit (SRU/TGU; evaluated for only Unit F-304, CO Boiler No. 2).

Additional control techniques were considered by Tesoro and are not listed here due to their lack of applicability to the Tesoro emission units. The following are more detailed descriptions of the NOX control and reduction technologies evaluated by Tesoro for use at the refinery. Control techniques that are applicable to only one or two units are specifically noted.

**Flue gas recirculation (FGR)** generally involves mixing some of the flue gas from the heater or boiler with the air fed to the burner(s). FGR can be integrated into the construction of the unit or can be added to an existing unit. In the FGR process, approximately 15 to 30 percent of the air supplied to the burner’s primary combustion zone is flue gas. The flue gas reduces the peak flame temperature and the local oxygen concentrations resulting in less thermal NOX formation. Thermal NOX is the principal kind of NOX produced in combustion of most gaseous and liquid fuels. FGR has been used on only a few oil refinery process heaters. These installations require extensive modification to the heater to accommodate the changed combustion characteristics and to avoid the introduction of hydrocarbon vapors that may leak from the heat transfer tubing to the flue gas.

Tesoro regards flue gas recirculation of flue gases at process heaters as an unacceptable safety risk due to the potential of formation of explosive gas mixtures in the event of a heater tube failure. Few applications have been made to refinery process heaters due to this risk. Therefore, this technology was not explored further.

**Low- and ultra-low-NOX burners** come in two principle designs: staged-air and the staged-fuel burners. Both function by adjusting the mixture of fuel and air to reduce peak temperatures and minimize the production of NOX. Some LNBs and ULNBs include flue gas recirculation in their design. Both designs generally have longer flame zones than the ‘standard’ burners that they replace in retrofit situations. The longer flame is not an issue in new heater installations due to the heaters being designed to accommodate the LNB or ULNB burners. Emission factors from EPA’s RACT/BACT/LAER Clearinghouse range from 0.08 to 0.1 lb/MMBtu (NOX) for LNBs and ULNBs.

LNB and ULNB retrofits are commonly installed as a result of BACT and LAER determinations or as a result of federal Consent Order requirements.

**Staged-air, low-NOX burners** limit NOX production by reducing flame oxygen concentrations in the primary combustion zone. The initial fuel combustion takes place in a fuel-rich, reducing atmosphere with a flame high temperature due to the low combustion air/fuel ratio. The low O2 concentration limits NOX formation.

---

6 (CPPI, 1990), (Campbell, 1991), (Martin, 1993), (Shareef, 1988)
For this burner design, retrofitting heaters with less than three feet between the burner and the opposite wall of the firebox may not be practical due to potential flame impingement on the firebox refractory materials or heat transfer tubes. Emission reductions achieved by staged-air LNBs range from 30 to 40 percent below emissions from conventional burners. Tesoro used a 40 percent NO\textsubscript{X} reduction for its initial cost analysis review.

**Staged-fuel, low-NO\textsubscript{X} burners** separate the combustion zone into two regions. The first is a lean primary region in which all the combustion air is injected with a small fraction of the fuel. This is followed by a second region where the remaining fuel is injected and combustion is completed.

Staged-fuel LNBs have several advantages over staged-air LNBs. First, the improved fuel/air mixing reduces the excess air necessary to ensure complete combustion. The lower excess air both reduces NO\textsubscript{X} formation and improves heater efficiency. Second, for a given peak flame temperature, staged-fuel LNBs have a more compact (shorter) flame than staged-air LNBs. Up to 72 percent NO\textsubscript{X} emissions reductions for staged-fuel LNBs have been reported over conventional burners based on vendor test data. Tesoro used a 60 percent average NO\textsubscript{X} reduction for its initial cost analysis review. Ecology has only included information using this version of LNB in the unit-specific discussions below.

**Ultra-low-NO\textsubscript{X} burners** (ULNBs) recirculate hot, oxygen-depleted flue gas from the flame or firebox back into the combustion zone. This reduces the average oxygen concentration within the flame maintaining the temperatures necessary for optimal combustion efficiency. ULNBs are physically larger than the conventional or LNB burners that might be used but compensate by having shorter flames than LNBs and are occasionally more efficient at combusting the fuel. They may require fans to provide combustion air rather than using a natural draft combustion air system. The conventional burner equipped heaters at Tesoro all use natural draft combustion air delivery systems. Burner mount modifications may be required because ULNBs usually do not fit into conventional burner mounts.

ULNBs now have the following features available:

- Compact sizes
- Shorter flame paths
- High turndown ratios

Tesoro used a 75 percent average NO\textsubscript{X} reduction for its initial cost analysis based on EPA methods. After receiving vendor guaranteed average NO\textsubscript{X} emission reductions ranging from 60 to 73.5 percent for specific units, Tesoro developed a vendor cost factor analysis for each unit based on the vendor guarantee and the unit-specific emission rate.

**Selective Non-Catalytic Reduction (SNCR)** is a post-combustion technology that involves directly injecting ammonia or urea into the hot flue gas. The reaction requires the flue temperatures required range from 1,600 to 1,750°F for ammonia and from 1,000 to 1,900°F for
urea-based reagents. Other chemicals such as hydrogen, hydrogen peroxide, fuel gas, and methanol may be added to improve performance and lower the minimum threshold temperatures. The injection point must be at a location where temperature of the flue gas is within the required temperature range for enough time for the reaction to occur.

Not all of the ammonia or urea is used. Unreacted ammonia in the emissions (ammonia slip) is potentially higher in SNCR systems than in an SCR system due to higher reactant injection ratios (2:1). The degree of ammonia slip can be minimized through consistent operation of the heaters and good operational controls.

Vendors contacted by Tesoro have projected potential NOX reductions at a maximum 25 ppm ammonia slip. SNCR systems may increase fuel gas consumption by approximately 0.3 percent in addition to the power required to vaporize aqueous ammonia. One result of the SNCR process is the formation of small amounts of nitrous oxide (N₂O), a greenhouse gas.

Ammonia used in the process is delivered and stored on site as either anhydrous ammonia or aqua-ammonia. If urea is used, it is delivered and stored as a dry material. Anhydrous and aqua-ammonia at concentrations above 19 percent ammonia require special reporting, handling, and worker safety requirements be followed. Urea is either dissolved in water and injected into the flue gas or converted to ammonia prior to injection.

SNCR may be used as the sole NOX control technique or in combination with LNBs or ULNBs. At optimum temperatures, NOX destruction efficiencies range from 30 to 50 percent. Tesoro used a 50 percent NOX reduction for its initial cost analysis review.

Vendor NOX reduction guarantees ranged from 35 to 40 percent based on Tesoro’s fuel gas compositions and measured bridgewall temperatures. EPA’s RACT/BACT/LAER Clearinghouse lists an emission limit of 127 ppmdv NOX at seven percent oxygen for a SNCR used to control emissions from a Fluid Catalytic Cracking Regenerator unit followed by a CO Boiler.

**NOX tempering (steam or water injection)** was proposed by Peerless Manufacturing Company as a technique that could be combined with SNCR on Units F-103 and F-304. Water or steam injection is a common NOX control for large combustion turbines permitted prior to 2000. Peerless proposed a patented process in which water is injected into the burner flame to reduce the peak flame temperature. For each 190°F of flame temperature reduction, the NOX is reduced by 50 percent.7 Peerless estimated that NOX tempering would reduce NOX formation by 30 to 35 percent.

Flame temperature cooling is likely to reduce bridgewall (a.k.a. arch) temperatures and thus reduce the heat energy available to heat the crude oil. To overcome this reduction in heat energy, fuel use in the two units would need to increase, but this potentially reduces the

---

effectiveness of tempering. Other potentially adverse effects are anticipated to occur. Finally, to date, NO\textsubscript{X} tempering has only been used on large utility boilers. Tesoro did not analyze this technique any further.

**Selective Catalytic Reduction** (SCR) is a post-combustion gas treatment technique to reduce NO\textsubscript{X} in the exhaust stream through the use of a catalyst. As with SNCR, an ammonia or urea solution is injected in the flue gas upstream of a catalyst bed where it selectively reduces the nitrogen oxide compounds in the exhaust to produce elemental nitrogen and water. The catalyst’s function is to reduce the reaction temperature from the range needed for SNCR.

Catalysts have been formulated to operate at three temperature ranges, a low temperature range based on platinum, and middle and high temperature catalysts based on a mixture of vanadium, titanium, and tungsten oxides. The operating temperature of the SCR system defines the catalyst type used. A conventional (middle range) SCR catalyst functions at temperatures of 600 to 750°F (the high temperature is often given as 850°F). Low temperature catalysts operate best in the range of 470 to 510°F. High temperature catalysts operate at temperatures of 900 to 1000°F.

Other than the catalyst bed reactor, major components of an SCR system are ammonia storage sources, vaporizer, and an ammonia injection grid. Catalyst deactivation and residual ammonia slip in the flue gas are the two key drawbacks in an SCR system. Catalyst activity decreases with operating time and with catalyst fouling. Disposal of the fouled catalyst presents another environmental concern due to the toxic metals contained in the catalyst. This concern is minimized as the result of the vendors recycling used catalysts.

Ammonia slip can be held to levels below five ppm in many situations, though the vendors contacted by Tesoro projected potential NO\textsubscript{X} reductions using a maximum slip of 25 ppm ammonia.

SCR catalysts will oxidize a small portion of the SO\textsubscript{2} in the flue gas to SO\textsubscript{3} which can combine with water vapor to form sulfuric acid mist.

Typical SCR NO\textsubscript{X} removal efficiencies range from 70 to 90\textsuperscript{%} percent removal, depending on the unit being controlled. Tesoro used a 90 percent NO\textsubscript{X} removal in its cost analyses.

The **LoTOx\textsuperscript{TM}** process is available from BELCO under license from BOC. It uses ozone to convert NO and NO\textsubscript{2} to N\textsubscript{2}O\textsubscript{5} which is removed from the flue gas by water where it is converted to nitric acid or is removed with a caustic scrubber and converted to a nitrate. Specifically, ozone (O\textsubscript{3}) is generated from industrial-grade oxygen using common industrial methods. O\textsubscript{3} is injected into the flue gas at a suitable, low temperature. O\textsubscript{3} oxidizes the NO\textsubscript{X} to N\textsubscript{2}O\textsubscript{5}. In a wet scrubber, the N\textsubscript{2}O\textsubscript{5} combines with water vapor in the flue gas to form nitric acid (HNO\textsubscript{3}). Following the reaction zone, multiple spray levels scrub the flue gas to absorb nitric acid mist.
and unreacted O₃ in the final step. The reported LoTOx™ NOₓ removal efficiency is 80 percent.⁸

NOₓ concentration changes in the flue gas do not adversely affect the removal efficiency of the LoTOx™ process. This means the Refinery Operations staff can optimize the combustion process to achieve the most cost-efficient burner conditions without considering NOₓ generation. Continuous NOₓ monitors within the system provide the O₃ flow rates necessary to achieve a set stack NOₓ level.

LoTOx™ systems require a downstream caustic or water based scrubber. The use of the water based scrubber would require either a use for the dilute nitric acid produced or a separate acid neutralization tank or other denitrifying wastewater treatment process. The scrubber must be compatible with the LoTOx™ system.

Currently, EDV® Wet Scrubbing systems with the LoTOx™ process for NOₓ control are installed on five Fluid Catalytic Cracking Units (FCCUs). One of these began operation in 2006 and the other units were commissioned during 2007. Tesoro considered adding LoTOx™ only to unit F-304, CO Boiler No. 2.

Use of a LoTOx™ unit with caustic scrubbing liquor will also produce a sodium or calcium nitrate-, sulfate-, and sulfite-rich wastewater which must be discharged to the plant’s industrial waste water system. The increased nitrates to the treatment system could have a beneficial or detrimental effect. Beneficial effects would come from reduced need to add nitrogen to the industrial treatment system for nutrient balancing of the biological treatment process. Detrimental effects could come from the need for denitrification in the final clarifier prior to discharge. Denitrification in the clarifier would result in increased total suspended solids in the effluent and could lead to violations of the refinery’s discharge permit. Tesoro did not perform a detailed evaluation of potential impacts.

A Sulfur Recovery Unit with Tail Gas Treatment (SRU/TGU) can be used to accept ammonia-rich vent gas from the Sour Water Stripper’s (SWS) second stage instead of burning it in F-304, CO Boiler No. 2. In this control option, the SWS vent stream would be rerouted from F-304 to a Sulfur Recovery Unit (SRU) where the ammonia would be converted to nitrogen gas rather than nitrogen oxides.

The Tesoro refinery does not operate its own SRU, but routes its H₂S acid gas stream to the SRU and sulfuric acid plant at the neighboring General Chemical facility. Due to a recent upgrade to the sulfur removal system at Tesoro and resulting increase in sulfides sent to it, the General Chemical facility has no additional sulfur processing capacity. The General Chemical facility cannot handle the ammonia-rich SWS gases.

Tesoro’s proposal to remove the ammonia-rich SWS vent gas stream from F-304 and treat it in an SRU requires construction of a new and independent SRU. The SRU would provide capacity

for future reductions of sulfur in the refinery fuel gas and in the fuel oils produced by the refinery.

The various emission controls described above are summarized in Table 2-1.

2.1.2 SO₂ Controls Evaluated for All Combustion Units

All BART-eligible combustion units are permitted to burn refinery fuel gas that has been treated to reduce the sulfur content or natural gas. While there are a number of add-on SO₂ control technologies available, at an oil refinery the most effective method is reduction of the fuel gas (refinery gas) sulfur content.

A review of the current information in the EPA RACT/BACT/LAER clearinghouse database indicates limited use of add-on SO₂ emission controls at oil refineries. The predominant control technology reported is “use of low sulfur fuel.” The exception to this is Catalyst Regenerator/CO Boiler stacks where add-on SO₂ controls are often included. The wet scrubber on Unit F-304, CO Boiler No. 2 is discussed in section 2.2.4 below. For its analysis, Tesoro focused on additional methods to reduce the sulfur content of the fuels used in the BART-eligible heaters and boilers.

Eliminating use of high sulfur fuel oil is a proven way to reduce SO₂ emissions from an oil refinery. This involves removal of the ability to fire fuel oil from the affected process heaters and boilers. The units may then be fired exclusively with natural gas, refinery fuel gas, or lower sulfur content distillate oil. At the Tesoro plant, only one of the BART-eligible units (Unit F-103) is still capable of firing a liquid fuel oil.

Tesoro evaluated additional flare gas recovery to reduce the amount of untreated gas burned in the flare system. Refinery fuel gas that is not used beneficially is sent to the plant flare system for combustion and disposal. Collection and routing of the recovered gas for use in the refinery fuel gas system reduces both the quantity of the gas flared and the sulfur content of the gas to match the level of the rest of the plant. Flare gas consists of purge gas, pilot burner gas (natural gas), various off gases associated with loading operations and process vents, and occasionally off gases from other process units during upsets, start-up, and shutdown conditions.

Converting equipment to run on exclusively natural gas is another method that can be used to reduce SO₂ emissions. The equipment is disconnected from the refinery fuel gas system and reconnected directly to a natural gas supply. This reduces SO₂ emissions because the total sulfur content of the natural gas is much lower than the refinery fuel gas. To implement this option requires installation of natural gas lines to all affected heaters and boilers or conversion of the entire plant to this option. Natural gas is a fuel that must be purchased and thus increases plant costs.

Natural gas can be added to the “fuel drum” where the refinery fuel gas is mixed with the natural gas. Many oil refineries use this practice to meet regulatory requirements, supplement limited refinery fuel gas, or reduce fluctuations in heat content and concentrations of hydrogen, ethane, propane, and butane in the fuel gas. Mixing pipeline or retail quality natural gas into the refinery fuel gas system involves routing a natural gas pipeline to the refinery gas fuel drum for mixing with the refinery gas. Tesoro already adds natural gas to its refinery fuel gas system.
**Refinery gas sulfur removal** is the most common method of treating refinery fuel gas. In this process, a solvent such as mono- or di-ethylamine is used to remove hydrogen sulfide and other reduced sulfides from the fuel gas. The untreated refinery fuel gas is “washed” with the amine. The sulfides preferentially attach to the amine solvent and are removed from the refinery fuel gas. The used amine solvent is routed to a regenerator system where the sulfide is thermally removed from the amine. The sulfides are routed to a sulfur recovery unit or similar process. The cleaned amine is then returned to the stripping process.

Provision for additional refinery fuel gas sulfur removal has been done within the current fuel gas cleaning system. The sulfur removed by the system must be routed to a sulfur recovery unit or sulfuric acid plant. Currently Tesoro is contracted with General Chemical to provide this service for the refinery. However, the General Chemical facility is at capacity and cannot accept more sulfur. As a result, Tesoro would need to construct a new sulfur recovery unit.

A new **Sulfur Recovery Unit (SRU)** is required to remove additional sulfur. Tesoro has evaluated the costs to install a new, 50 ton/day SRU at their plant as part of a project proposed in 2006. The capital cost was estimated to be $58 million to meet the federal New Source Performance Standard limit for refinery gas H$_2$S of 152 ppmv. Annual operational costs were not evaluated.

### 2.1.3 PM/PM$_{10}$ Controls for All Combustion Units

With the exception of emissions from Unit F-304, CO Boiler No. 2 discussed in section 2.2.4 below, PM/PM$_{10}$ controls applicable to the process heaters at this facility are tied directly to the use of fuel. Using low sulfur refinery fuel gas reduces potential particulate emissions as much as possible. The refinery gas system includes process steps to remove particulates and some heavier hydrocarbons from the refinery gas prior to being sent to the various fuel burning units. While reduction of fuel oil use in Unit F-103 is primarily to reduce SO$_2$ emissions, reduced or even total elimination of fuel oil combustion in this unit will also reduce PM/PM$_{10}$ emissions.

### 2.2 Evaluation of Controls for All Combustion Units

The subsections below evaluate plant-wide SO$_2$ reduction first and then the application of controls to each of the 14 combustion units subject to BART.

#### 2.2.1 Plant-Wide SO$_2$ Control

The Tesoro refinery has 14 combustion units subject to BART that emit SO$_2$. SO$_2$ results from the combustion of sulfur containing fuels such as the refinery fuel gas, natural gas, and fuel oil. Tesoro evaluated reduction of SO$_2$ from Units F-103 and F-304 and Flare X-819 individually and in combination with all other combustion BART units. Applicability of unit specific SO$_2$ controls on Units F-103 and F-304 and Flare X-819 are discussed in individual subsections below.
2.2.1.1 Evaluation of Plant-Wide Control

SO₂ controls at oil refineries have been studied by EPA who concluded that controlling refinery fuel gas sulfur content is the most efficient method to reduce SO₂ emissions from an oil refinery. The use of “low sulfur fuel” is the most common SO₂ control technique applied to oil refinery process units. “Low sulfur fuel” is usually defined as refinery fuel gas meeting the New Source Performance Standard (NSPS) requirements of 40 CFR Part 60, Subpart J.

In 2007 the Tesoro refinery upgraded the refinery gas sulfur removal system. The upgrade resulted in the refinery fuel gas with an average daily H₂S concentration of 70 ppm. However, short-term concentration “spikes” above 200 ppm can occur for several reasons, including rates of 1000 ppm when the sulfur recovery units or sulfuric acid plant is out of operation. This upgrade reduced the annual emissions of SO₂ from the refinery but not the short-term emissions. The refinery gas system upgrade was not subject to the New Source Review process but was included in OAC 952a issued by NWCAA as part of an order addressing installation of a larger amine system stripper gas pipeline to the sulfuric acid plant.

Sulfur removed from refinery products and the refinery fuel gas system is sent to the sulfur recovery and sulfuric acid production system operated by General Chemical. Tesoro owns the equipment for the system and contracts with General Chemical for operation and maintenance (O&M). General Chemical is responsible for all costs and environmental compliance. Currently the General Chemical plant is at capacity and unable to accept any additional sulfur from the Tesoro refinery. As a result any additional refinery fuel gas sulfur content reductions require the construction of a new sulfur recover unit.

Any additional reduction in refinery fuel gas sulfur content will require construction of a new SRU. In conjunction with a proposal to install a new coking system, Tesoro evaluated the construction of a new 50 ton/day SRU and refinery modifications to route sulfur streams to the new unit. The capital cost is estimated to be $58 million to continuously treat all refinery gas to the level of the NSPS standard (162 ppm of H₂S). Attributing all the cost to the SO₂ reductions to all combustion units (not just the BART eligible units) results in a plant wide reduction from the 2003 – 05 average emissions of 395 tons of SO₂ with a cost effectiveness of $16,100/ton of SO₂ (not including O&M costs). Tesoro also evaluated the cost effectiveness of continuously meeting a limit of 50 ppm of H₂S (a plant wide annual decrease of 451 tons per year), with the use of a new SRU. To meet a 50 ppm H₂S concentration would reduce the cost effectiveness to $14,100/ton, also not including O&M costs.

2.2.1.2 Proposed BART for SO₂

Tesoro proposed to continue use of the current refinery fuel gas system meeting the requirements of NWCAA’s OAC 952a for control of plant-wide SO₂.
2.2.2 Unit F-103, Crude Oil Distillation Heater

The Crude Oil Distillation Heater is used to heat crude oil for initial distillation steps. It has 24 burners split between two combustion cells. This 145 MMBtu/hr (average rate 103.5 MMBtu/hr) heater was constructed in 1963 and utilizes natural gas, refinery fuel gas, or fuel oil. Currently fuel oil is used as backup fuel to natural gas and refinery fuel gas, though there are no permit restrictions limiting the use of fuel oil in this unit. The burners used are of original equipment design and emit relatively high levels of NOX compared to current LNB or ULNB designs.

2.2.2.1 NOX Control

This heater currently uses “default” original manufacturer design burners originally installed in 1963. The current emission rates for this heater are an annual 121 tons per year (tpy) at an average concentration of 193 ppmv. After an evaluation of the technical feasibility of the NOX controls listed in Table 2-1, Tesoro evaluated the cost effectiveness of ULNB, SCR, SNCR, ULNB plus SCR, and ULNB plus SNCR. Table 2-2 lists pertinent criteria and cost effectiveness.

</tbody>
</table>

All of these controls are capable of being installed on this heater. Tesoro’s current understanding of the characteristics of potential ULNB burners suggests that flame impingement is not an issue and adequate space exists to install SCR. Installation of SNCR will reduce the gross heat available to heat crude oil. This reduction is due to the need to evaporate the water included in the aqua-ammonia used in the proposed SNCR system. Within the heat input capacity limits of the existing burners, this evaporation of water can be overcome by burning more fuel with an accompanying increase in emissions of other pollutants.

The most significant adverse impact resulting from SCR or SNCR is an increase in the amount of refinery fuel gas used to overcome heat losses. The increase in fuel use results in incrementally higher emissions of other pollutants from the combustion unit.
2.2.2.2 SO₂ Control

Tesoro evaluated the elimination of routine use of fuel oil combustion in Unit F-103 heater. This option results in a very small cost at this time and would reduce SO₂ emissions from the unit by about eight tpy (current SO₂ emissions are 160.5 tpy). If the actual use of fuel oil in this heater were higher, even approaching the annual heat input requirements of the heater, the SO₂ reductions would be even larger. Tesoro is concerned that in the future as the costs of fuel oil and refinery fuel gas change, fuel oil use could again become cheaper than natural gas/refinery fuel gas costs.

2.2.2.3 PM/PM₁₀ Control

Tesoro has evaluated ending the routine use of fuel oil in this heater as a BART technology. As noted above, the alternative has essentially no current cost to the plant and will reduce plant-wide PM emissions by about 26 percent or 7.7 tpy (the current emissions for this unit are 9.1 tpy).

2.2.2.4 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness and energy consumption and other non-air quality impacts. Based on that evaluation, they propose the installation of ULNBs as BART for NOₓ on this heater.

Tesoro has also proposed BART for SO₂ and PM/PM₁₀ for this heater as ending the routine use of fuel oil. Tesoro wants to retain fuel oil use in this heater to cover periods of natural gas curtailment, start-up, and shutdown of major process units in the refinery, and emergency conditions that would limit the availability of refinery fuel gas.

2.2.3 Unit F-104, Gasoline Splitter Reboiler

The Gasoline Splitter Reboiler is a heater used to heat the gasoline fraction from the Crude Distillation Unit for further distillation steps. It has six floor-mounted ULNB burners. This 53 MMBtu/hr (average rate 15.5MMBtu/hr) heater was constructed in 1972 and utilizes only refinery fuel gas.

2.2.3.1 NOₓ Control

This heater currently uses ULNBs installed in 2004. The current emission rates for this heater are 4.7 tpy, at an average concentration of 48 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NOₓ controls in Table 2-1, the only control evaluated for cost effectiveness for this heater was SCR. The average cost effectiveness of SCR was found to exceed $100,000/ton removed. No further analyses were performed.
2.2.3.2 Proposed BART

Based on their cost evaluation, the relative newness of the existing ULNBs installed in this unit and the high cost of SCR, Tesoro proposes the currently installed ULNBs as BART for NOX on this heater.

Tesoro’s continued use of the refinery fuel gas system as plant-wide SO2 BART applies to Unit F-104. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

2.2.4 Unit F-304, CO Boiler No. 2

The Unit F-304, CO Boiler makes use of the thermal energy in the carbon monoxide rich flue gas from the Fluid Catalytic Cracking Unit (FCCU) catalyst regenerator by combusting the gas and providing steam for many plant processes. This unit exhausts through a common stack with the other CO Boiler (F-302) which also receives off gas from the FCCU regenerator. Refinery fuel gas is used as a supplemental fuel when required. This unit is capable of operating as a conventional refinery fuel gas fired boiler when the catalyst regenerator is not operating. This 322 MMBtu/hr (average rate 184.5 MMBtu/hr) heater was constructed in 1964 and has four wall-mounted burners.

2.2.4.1 NOX Control

This boiler currently uses “default” original manufacturers design burners as originally installed in 1964. The current emission rates for this heater are 836 tpy. After an evaluation of the technical feasibility of the NOX controls in Table 2-1, Tesoro evaluated the cost effectiveness of ULNB, SCR, SNCR, ULNB plus SCR, and ULNB plus SNCR. Table 2-3 lists pertinent criteria and cost effectiveness.
Table 2-3. UNIT F-304 NO\textsubscript{X} CONTROLS EVALUATED IN DETAIL

Initially, Tesoro evaluated only the use of SNCR with the EPA method screen. Consultation with vendors and receipt of information on performance and price estimates resulted in the evaluation of the additional controls. All of these controls are capable of being installed on this heater.

The installation of SNCR will slightly reduce the gross heat available to provide steam. This reduction is due to the need to evaporate the water included in the aqua ammonia used in the proposed SNCR system. During normal operating rates, the heat input capacity limits of the existing burners is able to overcome this loss by burning more fuel, with an accompanying increase in emissions of other pollutants.

As noted above, the LoTO\textsubscript{X}™ system has been installed on very few other CO boiler/regenerator units. The installations provide both NO\textsubscript{X} and particulate control. The existing particulate and SO\textsubscript{2} control is incompatible with the acidic environment produced in the LoTO\textsubscript{X}™ process and cannot be retrofitted with the ozone injection step. The vendor has advised Tesoro that if replacement of the current Flue Gas Scrubber system were not possible, the LoTO\textsubscript{X}™ system would have to be installed after the Flue Gas Scrubber.\textsuperscript{10}

As an alternative to installation after the existing Flue Gas Scrubber, it could be replaced with a new LoTO\textsubscript{X}™ system and BELCO Wet Gas Scrubber. While not analyzed, the cost of removal of the 3-year old Flue Gas Scrubber and replacement with a new LoTO\textsubscript{X}™ system was considered to be very costly and was not evaluated.

\textsuperscript{9} Cost effectiveness shown is the lowest of the four analyses made. The differences in the four LoTO\textsubscript{X}™ cost analyses are primarily due to the cost of oxygen to produce ozone. The range of oxygen prices is $75/ton to $180/ton.

\textsuperscript{10} Response to questions regarding BART analysis, May 2, 2008, pp. 3-6.
### 2.2.4.2 SO\textsubscript{2} Control

The FCCU Catalyst Regenerator burns carbon contamination off of the catalyst to reactivate it. Sulfur in the catalyst contaminants is also oxidized in the catalyst regenerator step. Gases from the FCCU Catalyst Regenerator are exhausted to Units F-302 and F-304, CO Boilers.

The Flue Gas Scrubber installed on the stack for Units F-302 and F-304 (CO Boilers No. 1 and 2, respectively), provides a large decrease in SO\textsubscript{2} and sulfuric acid emitted. The scrubber was installed to comply with federal hazardous air pollutant (MACT) requirements for the FCCU Catalyst Regenerators. Tesoro selected the Flue Gas Scrubber over a cyclone particulate collector to meet the federal requirement because the scrubber also provided a significant SO\textsubscript{2} emission reduction.

### 2.2.4.3 PM/PM\textsubscript{10} Control

Unit F-304, CO Boiler No. 2 includes a Flue Gas Scrubber to remove particulate from the exhaust form the FCCU Catalyst Regenerator. This Flue Gas Scrubber was recently installed by the plant to comply with the MACT requirements to control emissions of particulate Hazardous Air Pollutants from the FCCU Catalyst Regenerator. At that time, Tesoro evaluated installation of an alternate particulate control device but chose to install the Flue Gas Scrubber instead. The choice was based on simplified maintenance, ability to comply with MACT standard, and the ability to reduce SO\textsubscript{2} and SO\textsubscript{3} emissions from the FCCU Catalyst Regenerator and CO Boilers No. 1 and 2. While only Unit F-304 (CO Boiler No. 2) is subject to BART, both boilers exhaust through a common stack.

### 2.2.4.4 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit.

Based on the original evaluation, Tesoro proposed the installation of low-NOX burners and SNCR as BART for NO\textsubscript{X} on this unit. However, this initial evaluation did not reflect the cost incurred by Tesoro for being required to take the F-304 boiler offline outside the normal turnaround schedule. With these costs included in the analysis, the use of the existing burners has been determined to be BART for NO\textsubscript{X}. See Section 2.4 for more information. BART for SO\textsubscript{2} and PM/PM\textsubscript{10} is the existing Flue Gas scrubber.

### 2.2.5 Unit F-6650, Catalytic Reformer Feed Heater

The Catalytic Reformer Feed Heater is used to heat the gasoline (naphtha) fraction for reforming into higher octane isomers. The heater has 10 floor-mounted burners and exhausts into two
common stacks with Units F-6651, F-6652, and F-6653. The heater is rated at 157 MMBtu/hr (average rate 124.7 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NOX compared to current LNB or ULNB designs.

2.2.5.1 NOX Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1971. The current emission rates for this heater are 144.7 tpy, at an average concentration of 172 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NOX controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB, ULNB, SCR, LNB plus SCR, and ULNB plus SCR. Table 2-4 lists pertinent criteria and cost effectiveness.

Table 2-4. UNIT F-6650 NOX CONTROLS EVALUATED IN DETAIL

</tbody>
</table>

All of these controls are capable of being installed on this heater. Flame impingement from LNB and ULNB burners is not an issue; however, there is inadequate space under the heater to retrofit ULNBs.

Adequate space exists to install SCR. Installation of an SCR system is evaluated for all four heaters because all four heaters exhaust to a common plenum leading to the two common stacks. The SCR addition can be done with or without a duct burner to raise the flue gas temperature. A duct burner would be fueled by refinery fuel gas. The costs for SCR presented in Table 2-4 are for the duct burner option. The non-duct burner option has a marginally different cost (see the Tesoro BART analysis report).

---

11 Refer to the Tesoro BART analysis for a more detailed description of how these heaters work together.
12 Averaged across Units F-6650, F-6651, F-6652, and F-6653.
2.2.5.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit.

In their original BART evaluation, Tesoro proposed the installation of LNBs as BART for NOX on this heater. However, this initial evaluation did not reflect the cost incurred by Tesoro for being required to take the F-6650 heater offline outside the normal turnaround schedule. With these costs included in the analysis, the use of the existing burners has been determined to be BART for NOX. See Section 2.4 for more information.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO$_2$ emissions from Unit F-6650. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

2.2.6 Unit F-6651, Catalytic Reformer Inter-Reactor Heater

The Catalytic Reformer Inter-Reactor Heater is used to heat the gasoline fraction at an intermediate point in the process of reforming gasoline into higher octane isomers. The heater has 16 floor-mounted burners in two connected fireboxes and exhausts into two common stacks with Units F-6650, F-6652, and F-6653. The heater is rated at 157 MMBtu/hr (average rate 90.4 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NO$_x$ compared to current LNB or ULNB designs.

2.2.6.1 NO$_x$ Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1971. The current emission rates for this heater are 104.7 tpy, at an average concentration of 171 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NO$_x$ controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB, ULNB, SCR, LNB plus SCR, and ULNB plus SCR. Table 2-5 lists pertinent criteria and cost effectiveness.

---

13 Refer to the Tesoro BART analysis for a more detailed description of how these heaters work together.

</table>

All of these controls are capable of being installed on this heater. Flame impingement from LNB and ULNB burners is not an issue; however, there is inadequate space under the heater to retrofit ULNBs.

Adequate space exists to install SCR. Installation of an SCR system is evaluated for all four heaters because all four heaters exhaust to a common plenum leading to the two common stacks. The SCR addition can be done with or without a duct burner to raise the flue gas temperature. A duct burner would be fueled by refinery fuel gas. The costs for SCR presented in Table 2-5 are for the duct burner option. The non-duct burner option has a marginally different cost (see the Tesoro BART analysis report).

2.2.6.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit.

In their original BART evaluation, Tesoro proposed the installation of LNBs as BART for NOX on this heater. However, this initial evaluation did not reflect the cost incurred by Tesoro for being required to take the F-6651 heater offline outside the normal turnaround schedule. With these costs included in the analysis, the use of the existing burners has been determined to be BART for NOX. See Section 2.4 for more information.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO\textsubscript{2} emissions from Unit F-6651. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

\textsuperscript{14} Averaged across Units F-6650, F-6651, F-6652, and F-6653.
2.2.7 Unit F-6652, Catalytic Reformer Inter-Reactor Heater

The Catalytic Reformer Inter-Reactor Heater is used to heat the gasoline fraction at an intermediate point in the process of reforming gasoline into higher octane isomers. The heater has seven floor-mounted burners which exhaust into two common stacks with Units F-6650, F-6651, and F-6653.15 The heater is rated at 74 MMBtu/hr (average rate 41.7 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NOX compared to current LNB or ULNB designs.

2.2.7.1 NOX Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1971. The current emission rates for this heater are 17.1 tpy, at an average concentration of 61 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NOX controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB, ULNB, SCR, LNB plus SCR, and ULNB plus SCR. Table 2-6 lists pertinent criteria and cost effectiveness.

</tbody>
</table>

All of these controls are capable of being installed on this heater. Flame impingement from LNB and ULNB burners is not an issue. ULNBs were found to be a good technical fit due to adequate space under the heater. The ULNBs proposed by the manufacturer would have a NOX emission rate of about 1/3 of their alternate LNB units at a 50 percent increase in cost.

Adequate space exists to install SCR. Installation of an SCR system is evaluated for all four heaters because all four heaters exhaust to a common plenum leading to the two common stacks. The SCR addition will require a duct burner to raise the flue gas temperature enough to

15 Refer to the Tesoro BART analysis for a more detailed description of how these heaters work together.

consistently meet the temperature requirements of a SCR catalyst. The duct burner would be fueled by refinery fuel gas.

2.2.7.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit.

In their original BART evaluation, Tesoro proposed the installation of ULNBs as BART for NOX on this heater. However, this initial evaluation did not reflect the cost incurred by Tesoro for being required to take the F-6652 heater offline outside the normal turnaround schedule. With these costs included in the analysis, the use of the existing burners has been determined to be BART for NOX. See Section 2.4 for more information.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO2 emissions from Unit F-6652. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

2.2.8 Unit F-6653, Catalytic Reformer Inter-Reactor Heater

The Catalytic Reformer Inter-Reactor Heater is used to heat the gasoline fraction at an intermediate point in the process of reforming gasoline into higher octane isomers. The heater has three floor-mounted burners which exhaust into two common stacks with Units F-6650, F-6651, and F-6652.17 The heater is rated at 42 MMBtu/hr (average rate 31.4 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design, emitting relatively high levels of NOX compared to current LNB or ULNB designs.

2.2.8.1 NOX Control

This heater currently uses “default” original manufacturer design burners as originally installed in 1971. The current emission rates for this heater are 13 tpy, at an average concentration of 61 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NOX controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB, ULNB, SCR, LNB plus SCR, and ULNB plus SCR. Table 2-7 lists pertinent criteria and cost effectiveness.

---

17 Refer to the Tesoro BART analysis for a more detailed description of how these heaters work together.

All of these controls are capable of being installed on this heater. Flame impingement from LNB and ULNB burners is not an issue. ULNBs were found to be a good technical fit due to adequate space under the heater. The ULNBs proposed by the manufacturer would have a NO\textsubscript{X} emission rate of about one-third of their alternate LNB units at a 50 percent increase in cost.

Adequate space exists to install SCR. Installation of an SCR system is evaluated for all four heaters because all four heaters exhaust to a common plenum leading to the two common stacks. The SCR addition will require a duct burner to raise the flue gas temperature enough to consistently meet the temperature requirements of a SCR catalyst. The duct burner would be fueled by refinery fuel gas.

#### 2.2.8.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit.

In their original BART evaluation, Tesoro proposed the installation of ULNBs as BART for NO\textsubscript{X} on this heater. However, this initial evaluation did not reflect the cost incurred by Tesoro for being required to take the F-6653 heater offline outside the normal turnaround schedule. With these costs included in the analysis, the use of the existing burners has been determined to be BART for NO\textsubscript{X}. See Section 2.4 for more information.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO\textsubscript{2} emissions from Unit F-6653. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM\textsubscript{10}.

\textsuperscript{18} Averaged across Units F-6650, F-6651, F-6652, and F-6653.
2.2.9 Unit F-654, Catalyst Feed Hydrotreater Heater

The Catalyst Feed Hydrotreater Heater is used to heat the deasphalted heavy oil fraction from the crude unit prior to sulfur removal in the hydrotreater. The heater has three floor-mounted burners. The heater is rated at 16.5 MMBtu/hr (average rate 7.6 MMBtu/hr). The heater was constructed in 1964 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NO\textsubscript{X} compared to current LNB or ULNB designs.

2.2.9.1 NO\textsubscript{X} Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1964. The current emission rates for this heater are 2.6 tpy, at an average concentration of 52 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NO\textsubscript{X} controls in Table 2-1, Tesoro evaluated the cost effectiveness of ULNB, SCR, and ULNB plus SCR. Table 2-8 lists pertinent criteria and cost effectiveness.

</tbody>
</table>

All of these controls are capable of being installed on this heater. Adequate space exists to install ULNBs and SCR. ULNBs were found to be a good technical fit due to adequate space under the heater. A vendor provided the price quotation for ULNBs that could be installed in the heater.

A screening analysis using EPA cost estimating procedures was done for installation of an SCR system. As can be seen, the cost of SCR is extremely high, primarily due to the very low uncontrolled NO\textsubscript{X} emissions.

There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit.
2.2.9.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. Based on that evaluation, they propose the currently installed burners as BART for NO\textsubscript{X} on this heater.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO\textsubscript{2} emissions from Unit F-654. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM\textsubscript{10}.

2.2.10 Unit F-6600, Naphtha Hydrotreater Feed Preheater

The Naphtha Hydrotreater Feed Preheater is used to heat the naphtha fraction prior to sulfur removal in the naphtha hydrotreater. The heater has four floor-mounted burners. The heater is rated at 71.5 MMBtu/hr (average rate 46.3 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NO\textsubscript{X} compared to current LNB or ULNB designs.

2.2.10.1 NO\textsubscript{X} Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1971. The current emission rates for this heater are 18.9 tpy, at an average concentration of 61 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NO\textsubscript{X} controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB, ULNB, SNCR, and ULNB plus SNCR. Table 2-9 lists pertinent criteria and cost effectiveness.

All of these controls are capable of being installed on this heater. Adequate space exists to install ULNBs and SNCR. ULNBs were found to be a good technical fit due to adequate space under the heater and lower emissions than LNBs.

A screening analysis using EPA’s cost estimating procedures was done for installation of these controls. As can be seen, the costs estimated using EPA’s methods is extremely high, primarily due to the very low uncontrolled NOX emissions. A vendor provided the price quotation for ULNBs that could be installed in the heater.

2.2.10.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit. Based on that evaluation, they propose the currently installed burners as BART for NOX on this heater.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO2 emissions from Unit F-6600. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

2.2.11 Unit F-6601, Naphtha Hydrotreater Stabilizer Column Reboiler

The Naphtha Hydrotreater Stabilizer Column Reboiler is used to heat the naphtha fraction prior to sulfur removal in the naphtha hydrotreater. The heater has four floor-mounted burners. The heater is rated at 75 MMBtu/hr (average rate 48.3 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NOX compared to current LNB or ULNB designs.

2.2.11.1 NOX Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1971. The current emission rates for this heater are 19.8 tpy, at an average concentration of 61 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NOX controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB, ULNB, SNCR, and ULNB plus SNCR. Table 2-10 lists pertinent criteria and cost effectiveness.

A vendor provided the price quotation for ULNBs that could be installed in the heater.

2.2.13.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality
impacts resulting from any of these controls on this unit. Based on that evaluation, they propose the currently installed burners as BART for NOX on this heater.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO2 emissions from Unit F-6654. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

2.2.14 Unit F-6655, Catalytic Reformer Stabilizer Regeneration Gas Heater

The Catalytic Reformer Stabilizer Regeneration Gas Heater is used to heat the gasoline fraction at an intermediate stage in the reforming process. The heater has three floor-mounted burners. The heater is rated at 30 MMBtu/hr (average rate 11.5 MMBtu/hr). The heater was constructed in 1971 and utilizes refinery fuel gas. The burners used are of original equipment design and emit relatively high levels of NOX compared to current LNB or ULNB designs.

2.2.14.1 NOX Control

This heater currently uses “default” original manufacturers design burners as originally installed in 1971. The current emission rates for this heater are 3.3 tpy, at an average concentration of 55 ppmv. After an evaluation of technical feasibility to retrofit the heater with the NOX controls in Table 2-1, Tesoro evaluated the cost effectiveness of LNB and ULNB. Due to unit size, temperature profiles, and configuration, SCR and SNCR were not technically feasible. Table 2-13 lists pertinent criteria and cost effectiveness.

</tbody>
</table>

At the initial technical evaluations, all of these burner designs were viewed as being able to be installed on this heater. Upon receipt of more detailed information from the vendor, it was found that only a LNB could fit into the space in and under the heater. Flame impingement from the burners is not an issue.
A screening analysis using EPA’s cost estimating procedures was done for installation of all three varieties of burners. As can be seen, the costs estimated using EPA’s methods is extremely high, primarily to the very low uncontrolled NOX emissions.

A vendor provided a price quotation for LNBS that could be installed in this application. The vendor quoted removal efficiency is based on the expected and guaranteed emission rates of the burners proposed for installation. Their control efficiency is lower than the generally accepted removal rates of LNBs.

2.2.14.2 Proposed BART

Tesoro has evaluated the technically feasible controls for cost effectiveness, energy consumption and other non-air quality impacts. There is no adverse energy, air quality, or non-air quality impacts resulting from any of these controls on this unit. Based on that evaluation, they propose the currently installed burners as BART for NOX on this heater.

The unit is fueled by refinery fuel gas. Tesoro proposed its current use of refinery fuel gas to control SO2 emissions from Unit F-6655. The continued use of low sulfur refinery fuel gas minimizes potential particulate emissions as much as possible and is considered BART for PM/PM10.

2.2.15 Flare X-819

Flare X-819 is used to combust process vent gases and vapors from loading operations that are not routed to the refinery gas system and gases from emergency releases of tank and process vessels. The flare operates all the time, but its primary function is to allow for the safe emergency venting of various process units in the refinery. Operation of the flare during emergency venting situations prevents hazardous conditions from occurring at the Tesoro refinery as a result of the emergency release of hydrocarbon vapors near process heaters.

The flare is a 2-stage, steam assisted flare of the “smokeless” design, rated at 244 MMBtu/hr and 2.6 million standard cubic feet per day (million scfd) of flared gas (0.5 million scfd in first stage and 2.1 million scfd in second stage). The flare was constructed in 1971 and utilizes refinery fuel gas for the pilot light fuel. While the potential to emit is considerably higher, for modeling purposes if the flare operated continuously at the modeled flare gas flow rate, it would emit 43.8 tons of SO2 and 8.8 tons of NOx per year. Information presented indicates the flare meets the design criteria of 40 CFR 60.18 for elevated flares.

2.2.15.1 NOX, SO2, and PM/PM10 Control

There are no emission controls directly attributable to operation of flares. Reduction of routine flaring operations is the most common way to reduce non-emergency flare emissions. Tesoro already utilizes a flare gas recovery compressor and other measures to recover combustible gases
and route them to the refinery fuel gas system. Adding a second compressor would recover gas from additional emergency vents that are currently routed directly to the flare system.

Tesoro evaluated addition of a second flare gas recovery compressor to reduce emissions from the flare. They estimated that this would reduce SO$_2$ emissions by about 10 tpy, have a capital cost of $2 million and a cost effectiveness of $21,960/ton.

2.2.15.2 Proposed BART

Tesoro proposed that BART for operations of the flare system is continued operation of the current system.

2.3 Evaluation of Controls for Cooling Water Towers 2 and 2a

The cooling water towers are used to cool returned “process cooling water” to prepare it for reintroduction to the process cooling water equipment. Current emissions of PM/PM$_{10}$ from the cooling tower are approximately 0.2 lb/hr (0.88 tpy). The cooling towers were constructed in 1971 and include reasonable droplet drift control techniques for the time.

2.3.1 PM/PM$_{10}$ Control

Tesoro requested an estimate for replacement of the current cooling tower drift control with a state-of-the-art system to reduce PM/PM$_{10}$ emissions from the cooling tower. This estimate was “on the order of $150,000” and would provide an 80 to 90 percent reduction in cooling tower drift emissions. Assuming the only cost involved with new drift elimination system is the capital cost, the estimated cost effectiveness is $41,781. Tesoro noted that the particulate formed by cooling towers tends to be larger in size and deposit on the area immediately around the cooling towers.

2.3.2 Proposed BART

After consideration of the cost per ton reduced and the small quantity of PM/PM$_{10}$ that would be controlled, Tesoro proposed continued operation of the current system as BART for the cooling tower.

2.4 Compliance Schedule Based Considerations

Subsequent to the information submitted by Tesoro in 2008, Ecology and Tesoro entered discussions on the BART compliance schedule to install the emission controls proposed by Tesoro as BART. EPA Region 10 was asked to provide specific information on some aspects of the proposed compliance schedules.

The requirements for BART in 40 CFR Part 51, Subpart P include the following requirement addressing when a source is to meet the BART emission limitations.
A requirement that each source subject to BART be required to install and operate BART as expeditiously as practicable, but in no event later than 5 years after approval of the implementation plan revision.\(^\text{19}\)

Based on an anticipated implementation plan revision approval about December 2010, all BART controls would need to be in operation by December 2015.

The installation of the proposed controls on Unit F-103 would meet the two primary constraints on the project: it could be accomplished within the normal turn-around schedule and within five years of the anticipated approval date of the state SIP.

The work on the CO Boiler, F-304, and the 4 catalytic reformer heaters, units F-6650–6653, either had to be accomplished outside of the normal turn-around schedule or would not occur till more than five years after the Ecology anticipated date of SIP approval. For these 5 units, Tesoro initially proposed a schedule based on complying with the BART limitation 5 years after the Regional Haze implementation plan was approved by EPA, and that the implementation plan approval date would be no earlier that the end of 2012, unless that date was less than 3 years prior to the routine, scheduled turn-around. One result of this proposal is that for these units, the earliest compliance date would be 2017. The company also proposed a provision that would further extend the compliance date for these units into the future if the SIP were approved after 2014.

The extended BART compliance date request by Tesoro was presented to EPA Region 10. The region advised Ecology that the proposal did not meet the plain requirements of the regional Haze rules.

The basis for Tesoro’s proposed compliance dates relates to their schedule for turn-around activities. As appears common in the petroleum refining and other industries, the various process units at the plant are taken out of service for major maintenance and upgrades on a routine cycle between 1 and 7 years for industries in Washington. The petroleum refining industry takes process units out of service for major maintenance and upgrades at five year intervals. The refinery as a whole is never taken fully out of service, though work on primary processing units like the Crude Unit and the Catalytic Reformer significantly affect the quantity of refined products produced during those times.

Corporate policy for Tesoro requires the maintenance needs, modifications, and any desired upgrades to the units involved in a particular turn-around are determined three years before the work is completed. The 3 year period allows for identification of non-routine work or upgrades, planning level cost analysis and approval from plant and corporate management, followed by financing, design, and new equipment purchases, all of which need to occur prior to contracting for the work. Permitting with the local air pollution control agency is not started until financing is approved by company management and design is far enough along to allow the permitting

\(^{19}\) 40 CFR 51.308(e)(1)(iv)
process to begin. Permitting usually starts 12 to 18 months before the actual start of construction, depending on complexity of permitting.

Ecology has confirmed the outlines of this 3 year planning/construction process through contacts with other refineries and the management of the local air pollution control agency that oversees the 4 largest oil refineries in the Washington. In general this process is the same as at the other refineries, as is the 5 year period between turn-arounds.

CO Boiler 2 (F-304) and the catalytic reformer heaters (F-6650–6653) have a normal turn-around scheduled for 2012, less than 3 years after the BART order is issued, let alone the approval of the Regional Haze implementation plan, which Ecology anticipates to be the end of 2010. The next scheduled turnaround is scheduled for 2017.

As a result of Ecology’s requested and EPA’s confirmation that a 2017/18 BART compliance date did not comply with the requirements of the federal visibility rules, Tesoro investigated the costs to install the BART controls at a time other than the normal scheduled turn-around schedule, including accelerated installation in 2012. As a result, the cost to install the controls increases, not just in direct costs for installation of the controls, but in “lost opportunity” costs due to taking these units off-line for at an unanticipated time. The “lost opportunity costs” are a direct consequence of taking the units off line outside of the normal schedule. These costs are built into the planning and total cost of the routine turn-around schedule and as such are not an extraordinary cost in that context.

The process to retrofit an existing heater with new low NOx or Ultra low NOx heaters is not a simple process of turning the heater off, letting it cool sufficiently, unbolting the old burners and installing the new burners, and turning it back on, though that is in essence all that is done. The new burners have different flame length characteristics that need to be accounted for in revisions to the refractory brick in the heaters. The heater must be cool enough for a man to get inside to work on the refractory brick. The overall time to turn off the heater, cool it sufficiently to do the burner work, conduct test firings of the burners to assure the flame pattern is what it is supposed to be, and finally return the unit to service will take several weeks.

While the unit is off line, the remainder of the refinery either has to operate at reduced rate, or on purchased intermediate products purchased from others. The plant has inadequate storage tank capacity to handle an outage of the F304 and F-6650 – 6653 units and remain near full operating rate. The ‘lost opportunity cost” is an extraordinary expense associated with the off-cycle project. As such, this becomes a site specific consideration in the cost to implement the burner retrofits on the CO Boiler and heaters20.

---

20 “The cost analysis should also take into account any site-specific design or other conditions identified above that affect the cost of a particular BART technology option.” 40 CFR Part 51, Appendix Y, Section IV.4.a
For Unit F-304, installation of the BART controls off the normal schedule causes the cost effectiveness to install the originally proposed BART controls of low NOX burners and SNCR system to rise to $10,802/ton NOX reduced from the original $4,592/ton NOX reduced.

Similarly the costs to install the low and ultra low NOX burners proposed for the catalytic reformer heaters (F-6650–6653) also increases to $13,190/ton NOX reduced from the original $3,349/ton NOX reduced.

In this evaluation, Ecology also compared these costs for burner replacement to the costs reported by another Washington state petroleum refinery that is subject to BART. The costs reported by Tesoro are in line with the costs reported by that refinery before the “lost opportunity costs” are removed from that refinery’s cost calculations. At the other refinery, the “lost opportunity costs” are primarily due to the additional time required to install low NOx burners compared to a normal turn-around on the same unit.

As a result of the increased costs to install these controls “off schedule” Tesoro proposed that BART for NOX from these units is the existing burners.
3. VISIBILITY IMPACTS AND DEGREE OF IMPROVEMENT

The results of the Tesoro’s modeling are shown in Table 3-1 for all Class I areas within 300 km of the plant plus the Columbia River Gorge National Scenic Area. The table shows the maximum day impairment due to Tesoro, the highest of the annual, 98th percentile days for the three years modeled, and the 98th percentile day of the modeled 3-year period. Also shown is the modeled visibility impairment resulting from the BART controls proposed by Tesoro. The shaded areas indicate values above the 0.5 dv threshold used to determine if a source contributes to visibility impairment.

The modeled emission rates were derived from operating records of the units and reflect the highest 24-hour emission rates within the three years that were modeled except for Unit F-304. Subsequent to the three years of the modeling period, this unit had a Flue Gas Scrubber installed and permitted with significantly lower emission rates. The emissions for Unit F-304 were scaled downward to reflect the currently-permitted emission rate for SO₂. For the other units with proposed BART controls, the effectiveness of the BART control was applied to the baseline emission rate to estimate the effect of BART on visibility impacts. The modeled emission rates are shown in Table 3-2.

Ecology modelers have reviewed the modeling performed by Tesoro and have found that the modeling complies with the Modeling Protocol and produces a reasonable result.

The modeled emission reductions proposed in the 2008 BART analysis result in substantial reduction in the visibility impairment caused by Tesoro in the most heavily impacted Class I areas modeled. At the three most heavily impacted Class I areas, Olympic National Park, North Cascades National Park, and the Alpine Lakes Wilderness, Tesoro’s proposed BART controls would provide 0.2 to 0.5 dv reduction in visibility impairment in each of these areas.

4. ECOLOGY’S BART DETERMINATION

Ecology has reviewed the information submitted by Tesoro. We agree with Tesoro’s proposal for BART. Ecology’s determination of BART for Tesoro is shown in Table 4-1. In making its determination of BART for these units, Ecology reviewed the types of controls and emission rates required under EPA national Consent Orders issued to oil refineries and BACT and BART determinations or guidance from other states.

Units F-302 and F-304 both exhaust to the same particulate/SO₂ control device, the Flue Gas Scrubber. Currently the emission limitations attributable to the individual units and on the FCCR catalyst regenerator that feeds these two units are added together and regulated at the scrubber stack. For this BART determination, Ecology proposes to continue this practice for particulate and SO₂.

Ecology believes the NOₓ emission controls and resulting emission reductions originally proposed as BART by Tesoro are appropriate and cost effective to implement as part of a regularly scheduled turn-around project. These controls may ultimately be required to be installed in the future as further progress toward meeting the visibility goals. However, the increased costs to accomplish the burner and SNCR installations outside of the unit’s normal maintenance cycle, we determine that BART for Unit F-304 is the current emission controls and emission limitations.

Similar to Unit F-304, Ecology believes the emission controls and resulting emission reductions originally proposed as BART by Tesoro for the Catalytic Reformer Heaters F-6650–6653 are appropriate and cost effective to implement as part of a regularly scheduled turn-around project. These controls may ultimately be required to be installed in the future as further progress toward meeting the visibility goals. However, the increased costs to accomplish the low and ultra low NOₓ burner installations outside of the unit’s normal maintenance cycle, we determine that BART for Unit F-304 is the current emission controls and emission limitations.

As a result of the reduced NOₓ emission reductions proposed as BART by Ecology when compared to Tesoro’s initial BART proposal, the visibility improvement will be considerably less than was modeled by Tesoro and depicted in Section 3. Ecology has not remodeled the visibility improvement or required Tesoro to do so. Using only the 3-year, 98th percentile day at Olympic National Park as an example, we estimate that the visibility improvement due to this proposed BART determination to be about 0.1 dv, compared to Tesoro’s modeled improvement for their original proposed BART of 0.37 dv for the same day.
