Part III, Operating Unit 8-I.iii
ADDENDUM I

INSPECTION PLAN

I.1 INSPECTION PLAN
This section describes the method and schedule for inspections of the 222-S Operating Unit Group in accordance with WAC 173-303-320. The purpose of inspections is to ensure that malfunctions and deterioration, operator errors, and discharges are prevented, that may cause or lead to the release of dangerous waste constituents to the environment or a threat to human health. These inspections must be performed often enough to identify problems in time to correct them before they harm human health or the environment. In accordance with WAC 173-303-320(3), any problems revealed by the inspection must be remedied on a schedule that prevents hazards to the public health and environment. Where a hazard is imminent or has already occurred, remedial action must be taken immediately.

I.1.1 General Inspection Requirements
The content and frequency of inspections are described in this section. The inspections are performed by qualified personnel and controlled by laboratory management. Inspections are documented on inspection report forms. The schedule and inspection reports are retained in the operating record for at least five years and contain the following information:

- Date and time of inspection.
- Printed name and the hand-written signature of the inspector.
- Notation of the observations made.
- An account of spills or discharges in accordance with WAC 173-303-145.
- Date and nature of any repairs or remedial actions taken.

I.1.1.1 Types of Problems
Tables I.1, I.2, and I.3 describe for the types of problems looked for during an inspection.

I.1.1.2 Frequency of Inspections
Tables I.1, I.2, and I.3 describe the inspection frequencies that are required.

I.1.2 Schedule for Remedial Action for Problems Revealed
The 222-S Operating Unit Group organization remedies any problems revealed by the inspection on a schedule that prevents hazards to human health and environment. Where a hazard is imminent or already has occurred, immediate remedial action is taken. Immediate remedial actions are implemented based on ALARA considerations. Further remedial actions are documented in the facility corrective action management program.

I.1.3 Specific Process Inspection Requirements
The following sections describe the specific process inspections to be performed at 222-S DMWSA, Room 2-B, Room 4-E, and the 219-S Waste Handling Facility.

I.1.3.1 Container Inspection
Containers are inspected for evidence of deterioration of structural integrity and to ensure that dangerous waste labels and markings are legible, and waste labels and markings are not obscured, removed, or otherwise unreadable. All containers are stored closed with appropriate closure for
that container. Bulging, creasing, and rusting, which might be evidenced by peeling paint, are
recorded to initiate corrective action.

- Containers in storage areas are inspected weekly for leaks, spills, and deterioration
  caused by corrosion, rust, or other factors.
- Inspection report forms are kept in the 222-S Operating Unit Group’s operating record.
  For report forms that indicate findings, corrective action datasheets are completed and
  tracked for any abnormal conditions observed.

I.1.3.2 Tank System Inspection

Table I.1 lists the requirements for inspection of the 219-S Tank System. The tanks are located
within shielded vaults and are not readily accessible because of ALARA concerns. Daily
inspections include evaluation of data gathered from leak detection monitoring equipment, tank
level instrumentation. Annual verification/calibration of the high-level alarms and bimonthly
verification of cathodic protection is also required. The tank system has extensive process
controls and a microprocessor monitoring system linked to local and remote automated alarms.
Any leakage in the tank vault or transfer lines drains to floor sumps. Each sump has a liquid level
probe that when activated causes an alarm to sound in the 222-S Laboratory and in the 219-
S Waste Handling Facility operating gallery. Liquid collected in sumps is transferred back into
the tanks as long as WAC 173-303-640(7) requirements are met. The probability of a tank
overflow is very low based on tank system design and operating parameters such as setpoints for
high-level alarms, one-way pneumatic valves, and piping configuration (described in Addendum
C).
